# Outline

- Polynomially Verifiable
- Complete problems for P and NP

# Polynomially Verifiable Languages

- NP is sometimes called the class of languages which are polynomial time verifiable.
- Call a relation  $R \subseteq \Sigma^* \times \Sigma^*$  *polynomially decidable* if there a DTM which decides the language  $\{ \langle x, y \rangle \mid (x, y) \text{ is in } R \}$ . We say  $R$  is *polynomially balanced* if  $(x, y) \text{ is in } R$  implies  $|y| \leq |x|^k$  for some  $k \geq 1$ .

- The next proposition shows what polynomial time verifiable means

**Prop.** Let  $L$  be a language.  $L$  is in NP iff there is a polynomially decidable and polynomially balanced (by  $|x|^k$  for some  $k$ ) relation  $R$ , such that

$$L = \{ x \mid \exists y, |y| \leq |x|^k \text{ and } (x, y) \text{ is in } R \}$$

- So given  $x$ , if we had in  $|x|^k$  proof string  $y$  we could verify in polynomial time whether  $x$  was in  $L$ .

**Proof.** Any  $L$  of the form  $\{ x \mid \exists y, |y| \leq |x|^k \text{ and } (x, y) \text{ is in } R \}$  can be decided in NP by a machine which first nondeterministically guesses  $y$  and then runs  $R$  on  $(x, y)$ . On the other hand, if  $L$  is NP via  $M$ , some NDTM, then we can let  $R$  be the  $p$ -time DTM which acts like  $M$  except when  $M$  needs to do its  $i$ th nondeterministic move,  $R$  instead consults the  $i$ th square of  $y$  and uses this value to say which possible next transition to follow.

# Variations on SAT

- $k$ -SAT is the variant of SAT where each clause has at most  $k$  literal.

**Prop.** 3SAT is NP-complete.

**Proof.** Notice our reduction of CIRCUIT-SAT to SAT is actually a reduction to 3SAT.

**Prop.** 3SAT remains NP-complete for expressions in which each variable appears at most three times and each literal at most twice.

**Proof.** Suppose a variable  $x$  appears  $k$  times in a 3SAT instance. We would replace this variable with  $k$  variables  $x_1, \dots, x_k$  and add the clause:  $(\neg x_1 \vee x_2) \wedge (\neg x_2 \vee x_3) \dots \wedge (\neg x_k \vee x_1)$

# 2SAT is in P

Given a 2SAT instance  $I$  we can build a graph  $G(I)$  as follows:

- the vertices of  $V$  are the variables of  $I$  and their negations.
- there is an edge  $(a,b)$  in the graph iff there is a clause  $(\neg a \vee b)$  in  $I$ .  
These edges can be viewed as capturing logical implication

**Thm** One can show  $I$  is unsatisfiable iff there is a variable  $x$  such that there are paths from  $x$  to  $\neg x$  and from  $\neg x$  to  $x$  in  $G(I)$ .

**Proof.** Suppose such a path exists then assigning  $x$  true and following the path of implications gives  $\text{true} \Rightarrow \text{false}$ . Similarly, if one assigned  $x$  false.

On the other hand if there is no such path, we could pick a node  $a$  that has not been assigned and such that there is no path from  $a$  to  $\neg a$ , and assign it true. We also assign true all nodes reachable from  $a$  and assign false the negations of these nodes. Then we repeat.

This proves 2SAT is in P since reachability is in P-time.

# 2SAT is in NL

Recall NL is closed under complement. So it suffices to recognize unsatisfiable expression in NL. In NL, we guess a variable  $x$  and a sequence of successive pairs of vertices along a path from  $x$  to  $\neg x$  and back.

# MAX2SAT is NP-complete

- MAX2SAT is the problem give a 2SAT instance I, and an integer k: Is there an assignment which makes at least k clauses true?

**Thm.** MAX2SAT is NP-complete.

**Proof.** Consider the ten clauses:

$(x)(y)(z)(w)$

$(\neg x \vee \neg y) (\neg y \vee \neg z) (\neg z \vee \neg x)$

$(x \vee \neg w) (y \vee \neg w) (z \vee \neg w)$

There is no way to satisfy all these clauses. Notice if a truth assignment satisfies  $(x \vee y \vee z)$  then we can satisfy 7 of these clauses. For all other truth assignments we can satisfy at most 6. So we can use this to reduce a 3SAT instance of m clauses to a MAX2SAT instance with  $k=7m$ .
