Checklist:

We will be mainly looking at two files. The first is `articles_controller.rb`. In this file you can see that, in the `ArticlesController` class, before anything can happen, the system must first authenticate the user. This means that the system will make sure the user is properly logged in with an account.

After this test we proceed to the `index.html.erb` file. Once in this file, since the user has already been authenticated, we proceed to populate the screen with the list of reservations. The list of reservations is displayed. Next to the reservations buttons are created to Edit and/or Delete the reservation

Description:

The use case that we will be examining will be of a visitor to the restaurant viewing the current queue of reservations. The first thing that happens in this case is that the system checks to see if the user is logged in. If the user is correctly logged in, then the website will proceed to the view queue page. This page is then populated with a list of the current active reservations. The system also makes available Edit and Delete buttons for the user to modify his or her reservation.
