

Concurrency Control w/o Locking

Use timestamps $TS(T_i)$ indicating start time of T_i

Want that if a_i of T_i is operation that conflicts w/ a_j of T_j then if $TS(T_i) < TS(T_j)$ a_i occurs before a_j . Otherwise, abort transaction ~~of T_i~~

To get this to work every ~~transaction~~ object ^{timestamp} is given a read timestamp $RTS(O)$ and a $WTS(O)$. If T wants to read O and $TS(T) < WTS(O)$ then abort T and restart w/ largest timestamp. If $TS(T) > WTS(O)$, T reads O and $RTS(O)$ is set to larger of $RTS(O)$ and $TS(T)$. If T wants to write if $TS(T) \leq WTS(O)$ abort.

If $TS(T) < WTS(O)$ might abort but don't if follow Thomas Write rule in w/c case write and update $WTS(O)$. Otherwise T writes O & updates $WTS(O)$.

Fact: using Thomas Write Rule can lead to uncontrollable schedules

~~Above shown~~

Crash Recovery

Recovery manager - responsible for atomicity and durability of transactions

undo transactions
that don't commit

makes sure all
committed transactions
survive crashes

ARIES - popular recovery algorithm
Phases after a crash uses ~~state~~ - no force approach not forced
objects can be written to disk before commit if committed

① Analysis - identifies dirty pages in buffer pool
as well as active transactions at time of crash.

② Redo : Repeats all actions, starting from an appropriate point in the log to get DB into state at time of crash.

③ Undo : Undoes actions that did not commit.

Ex	Log Sequence Number (LSN)	LOG
Log Fd	10	+ update T1 writes P5
	20	+ update T2 writes P3
	30	- T2 commit
	40	- T2 end
	50	+ update : T3 writes P1
	60	+ update : T3 writes P3
		X crash

Logs 10, 20, 30, 40, 50, 60. T3 and T1 were active at time of crash. T2 committed and undone.

3 Main Principles of Aries

- Write ahead logging: Any change to DB first record to the log. This ~~change~~ must be on disk or logs before the change to the DB written to disk
- Repeating History During Undo: Repeating operation up to point of crash then undo ops as necessary
 - allows record level locking
- Logging Changes During Undo: Changes made while undoing transactions are logged to ensure such an action is not repeated if crash while recovering.

What ~~should~~ does a log entry look like?

prevLSN	transID	type	pageID	length	offset	before	after
link to previous transaction recorded LSN by this transaction	↑ ↑ ↑ ↑ ↑	update commit abort end undo	↑ ↑ ↑ ↑ ↑	↑ ↑ ↑ ↑ ↑	↑ ↑ ↑ ↑ ↑	↑ ↑ ↑ ↑ ↑	↑ ↑ ↑ ↑ ↑

indicates part of page changed.
force-writes log record and log-tail

Compensation Log Record (CLR)

- a log record for undoing an operation written when a transaction aborted and start undoing its operation
- Also written during undolog phase of crash recovery.
